# SUMMARY OF ILLINOIS FARM BUSINESS RECORDS

Commercial Farms:

PRODUCTION COSTS INCOME INVESTMENTS

UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN COLLEGE OF AGRICULTURE COOPERATIVE EXTENSION SERVICE CIRCULAR 1006

### Source of Data

This report is based on data obtained from farm business records on 6,500 Illinois farms. It is the 44th in a series of annual summaries of such records obtained from farmers cooperating with the University of Illinois Cooperative Extension Service, the Department of Agricultural Economics, and the Illinois Farm Business Farm Management Association.

At present about 1 out of every 10 full-time commercial farmers (farmers with \$10,000 or more of gross sales) in Illinois is enrolled in this service. The service has grown steadily, and in 1969 there are 10 associations in 102 counties served by 42 full-time fieldmen. Participation in this farm business analysis service is voluntary, and cooperating farmers pay a fee for the services received.

The development since 1940 is shown by the following figures:

Year	Associa- tions	Counties partici- pating	Fieldmen employed	Farmers enrolled
1940	3	23	3	680
1945	8	54	9	1,830
1950	8	59	15	2,760
1955	9	89	24	4,501
1960	10	100	33	5,494
1965	10	102	39	6,366
1969	10	102	42	6,565

Over 98 percent of the 6,500 farms in this report fall within the size of business of Economic Class I, II, and III as defined in the 1964 Census of Agriculture. These three classes include farms selling \$10,000 or more of farm products a year.

The segment of Illinois agriculture that includes Economics Class I, II, and III farms is often referred to as "commercial farming." In 1964, there were 68,322 farms in Illinois with more than \$10,000 of product sales. These farms represented 52 percent of the total number of farms and produced nearly 90 percent of the products sold from Illinois farms.

Although the record-keeping farms in this report are largely within the first three economic classes, they are not proportionately distributed among the groups. In 1964, the Census of Agriculture identified 3,832 Illinois farms with more than \$60,000 in sales. Over one-third (34 percent) of these farms were enrolled in the Illinois Farm Business Farm Management Association. Of the 6,152 farms that sold from \$40,000 to \$59,000 of products, 24 percent participated in the farm record program. There were 32,881 Economic Class III farms in the 1964 Census of Agriculture (farms with sales ranging from \$10,000 to \$19,999). Only 730, or 2.2 percent, of these farms were enrolled in the record-keeping program.

The data presented in this report are group averages identified by size of business, type of farm, and quality of soil found on the farm. Where segments of Illinois agriculture are identified by these criteria, the data from record-keeping farms may be used with reasonable confidence, even though the record-keeping farms as a group do not represent a cross-section of all commercial farms in the state.

## Uses for This Report

The management of a modern commercial farm involves decision making in the application of technology, the choice of a proper combination of crop and livestock enterprises, and effective business administration of the farming operations. A basic farm business analysis involves a careful study of past performance to detect problem areas and strengths in the farming operation. Also involved is the process of planning and developing future operations to attain the full potential of the land, labor, and capital resources available and to improve economic efficiency of the farm business.

The farm business summaries contained in this report are used by individual farmers to analyze their business operations and as a basis on which to develop plans for future farming operations. This report summarizes the information so that specialists working in agricultural extension, research, teaching, and agribusiness activities may use the data to assist them in the effective performance of their duties.

The data are presented in three sections. In the first part of the report (Tables 1 to 4), farm business trends and recent changes in farm income on Illinois farms are summarized. Economic forces and factors that contribute to these changing trends are identified.

In the second section, detailed livestock enterprise data are presented. These data (Tables 5 to 14) provide comprehensive and detailed information for use as resource data by all who are interested in livestock production. Because a large proportion of the feed grains and roughage produced on Illinois farms is marketed through livestock, the margins of income from livestock enterprises are important in interpreting the economic results of farming operations.

The third section (Tables 15 to 19) reports costs, returns, financial summaries, investments, land use, and crop yields for different sizes and types of farms in northern and southern Illinois. The definitions of terms and accounting measures that precede these tables will aid in using the data.

TREC AGX

# **SUMMARY OF ILLINOIS FARM BUSINESS RECORDS, 1968**

#### Farm business trends in 1968

Illinois agriculture is based largely on crop production, especially the corn and soybean crops. The total value of corn and soybeans produced on Illinois farms in 1968 was equal to 54 percent of the total cash sales of crops, livestock, livestock products, and government payments in the same year. The five major crops of corn, soybeans, wheat, oats, and hay harvested were equal in value to 62.8 percent of the cash sales on Illinois farms in 1968.

Year-to-year variations in net farm income are related to variations in crop yields. In 1968 Illinois farmers produced record yields of soybeans and oats. Corn and wheat yields were below 1967 yields. Crops were generally planted under adverse conditions, but harvest weather was nearly ideal. While early crop reports indicated record high corn yields, unfavorable growing conditions at pollination and silking stages caused yields to be lower than expected.

In 1968 corn yields for the state, as recorded by the Illinois Crop Reporting Service, were 89 bushels per acre, 11 bushels below the average yield of 100 bushels in 1967, and 5 bushels below the previous record yield in 1965. Soybean yields in 1968 were 31.5 bushels per acre, 0.5 bushel above the 1967 yield and highest on record. Winter wheat yields were 36 bushels per acre, 5 bushels below the record high yield established in 1966. Corn and wheat acreage harvested was down 6 and 20 percent respectively from 1967, while soybean acreage was up 8 percent.

Crop and livestock prices. A second major determinant of change in farm income is the price farmers receive for crop and livestock products. In 1968 market prices received by farm account cooperators for farm crops were below the 1967 prices for all major

Table 1. - Adjustments on Illinois Farms

	1961-62	1965–66	Change per farm

	147,916	196,320	48,404
Feed and grain returns  Cash operating expenses and depreciation  Total non-feed costs  Value of farm production	22,146	31,542	9,396
	15,839	22,326	6,487
	25,250	34,936	9,686
	30,475	45,026	14,551
Management returns	5,225	10,090	4,865

grain products (see Table 14). Market prices for hogs averaged \$18.54, down from the \$18.85 received in 1967. Prices received for slaughter steers and heifers averaged \$26.29, up \$1.31 from the average price of a year earlier. Egg prices averaged 34 cents a dozen, up 4 cents from the 30 cents received in 1967. Milk prices averaged \$4.89 per 100 pounds in 1968, up 22 cents from 1967 and up \$1.12 from 1965.

Farm adjustments. According to the Census of Agriculture, the average Illinois farm in 1964 contained 226 acres, compared with 196 acres per farm in 1959. Physical changes and changes taking place in investments, costs, and returns on record-keeping farms are shown in Table 1. The average results for 1961-62 were compared with those for 1965-66 on the same farms.

These results came from a study of 183 farmers who kept continuous records from 1961 to 1966. An equal number of hog, grain, and beef farms were selected from the northern two-thirds of the state. These were combined with an equal number of grain, hog, and dairy farms from the southern Illinois area.

The average age of the farm operators at the beginning of the period was estimated at 41. The U.S. index of prices received (1957-59 = 100) was 100 for 1961-62 and 106 for 1965-66. The index of prices paid was 105 for 1961-62 and 114 for 1965-66. Prices received were higher in 1965-66 than 1961-62 on record-keeping farms by 19 cents per bushel for corn, \$5.44 per 100 pounds for hogs, 30 cents per 100 pounds for milk, and 6 cents per 100 pounds for cattle.

Acres per farm increased in this four-year period by 33 acres or about 8 acres per year. If this trend continues, the average size farm will be 475 to 500 acres by 1980. The total months of labor used changed very little. Livestock farms dropped a month from 23 months used at the beginning of the period. Grain farms stayed at 20 months. All farms averaged using about 20 months.

Even with a fixed labor supply the average farmers were adding acres to their farms, increasing their acreage of corn and soybeans, and increasing the size of their livestock enterprises each year. Note the \$48,404 (\$12,101 per year) increase in total investment per farm to operate these larger businesses. About 82 percent of this increase was caused by more land in the farm and higher land values. But the upward trend is also shown in the \$3,813 per farm increase in machinery investment.

It took \$6,487 (\$1,621 per year) more cash in this four-year period for operating expenses and deprecia-

tion allowances. Major increases occurred in the expenditures for fertilizer, seed, herbicides, and insecticides.

During this period, the value of production on livestock farms showed a greater increase than on grain farms. The very favorable hog prices in 1965 and 1966 contributed to these higher returns. Results from 1967 and 1968 records show that returns are down, especially on grain farms. But costs continued their upward trend.

A similar study of 109 central Illinois farms comparing 1951-52 with 1958-59 showed almost identical rates of change as shown here for the sixties. If costs continue to increase, it will be necessary to allow for growth in the farm business in order to remain competitive. Growth with a constant labor supply means more capital per man. Management requirements will become more precise, and good financial management will be the key to success.

#### Income changes on Illinois farms

Comparative costs and returns between years and among major types of farming in northern and southern Illinois are reported in Tables 2 to 4. The separation of farms into northern and southern Illinois is based on soil-type regions, and divides the state approximately on an east-west line from Mattoon to Jacksonville. The sample of farms ranged between 260 and 339 acres in size, and averaged about 300 acres. Labor used on farms of this size averaged 14 months on grain farms, 16 months on hog and beef farms, and 19 months on dairy farms. The data in these tables are presented as if the farms were all owner-operated. Landlord and tenant shares of the business were combined where farms were leased.

Size of farm, type of farm, quality of soil, and managerial inputs were held reasonably constant over time by the sampling procedure used in selecting farms within each type of farm. Variations among 1967, 1968, and the 10-year average are due to changes in farm prices and costs, weather, and internal farming adjustments made within each system of farming. The data in these tables are particularly helpful for evaluating changes in farm costs and returns within a particular size and type of farm, and in making comparisons between types of farming. The data do not reflect overall farming adjustments resulting from farm enlargement or major changes in resource use (see Table 1).

<sup>&</sup>lt;sup>a</sup> Includes sales or purchases of capital items.

The farm and family earnings measure includes returns to the farm family for all unpaid labor, interest on invested capital, and managerial inputs used in farming. Changes in value of farm inventories and value of farm products consumed are included as income. Farm and family earnings are calculated by accounting methods that are generally comparable to the accrual method of calculating taxable farm income for the federal income tax. Important differences in accrual income tax accounting methods are the provision for capital gains on livestock sales and the inclusion of interest paid as a farm expense.

The cash balance figure is the amount taken out of the farm business to pay for living costs, income and social security taxes, interest, debt repayment, and to add to savings. Purchases of new capital investments for the farm business have been included with total cash expenditures. Although the cash balance figure reflects the cash position of the farm business, it is influenced by purchases and sales of feed and livestock and by changes in liabilities and borrowed funds.

The investment per farm is for January 1 of each

year. Physical quantities of grain and livestock are valued at farm market prices. Machinery, buildings, soil fertility, and auto are valued at remaining capital cost; that is, original cost less depreciation charged to date. Land is priced at current values. A basic value is established for each farm, based on a soil productivity rating, and is adjusted to a current value each year by using an index of land prices in Illinois.

#### Northern Illinois farms

Grain farms. Farm and family earnings on northern Illinois 300-acre grain farms in 1968 were \$10,925 compared with \$13,569 in 1967 (see Table 2). Most of the decrease in net income was caused by higher costs and by lower values on the grain inventory at the end of the year. Corn yields decreased 14 bushels per acre while soybean yields increased 3 bushels per acre over 1967. Farm costs increased \$1,931 per farm while all inventory values of grain and livestock dropped \$2,919 per farm from 1967. This combination of higher costs and lower returns resulted in the lowest returns for resources used on this size grain farm since 1959.

Hog farms. Farm and family earnings on 300-acre northern Illinois hog farms were \$15,158 in 1968 compared with the 10-year average (1959 through 1968) of \$15,108 (see Table 2). Steady hog and strong beef prices helped offset the effect of lower grain prices and lower corn yields in 1968 as compared with 1967 in maintaining the total value of farm production.

Farm costs increased \$1,575 per farm over the 1967 costs, with the greatest increase in labor cost. Constant value of farm production, combined with the higher costs, resulted in the lowest returns to resources used on this size hog farm since 1963. While the average pounds of pork produced per farm has increased 28 percent since 1960-61 to about 100 litters, there is still need for increasing the output each year to compensate for the loss in income caused by increased costs.

Dairy farms. Farm and family earnings on 300-acre northern Illinois dairy farms in 1968 were \$15,059 compared with \$14,461 in 1967 and \$12,939 for the 1959-68 average. The higher milk price of 22 cents per hundredweight for milk sold was offset by lower prices for crops produced. Cash operating expenses actually decreased \$1,832 per farm, but labor and interest charges were up \$794. In 1968 the \$15,059 return on dairy farms was \$4,134 more than grain farms of similar size and only \$99 below hog farms of similar size.

Beef farms. Farm and family earnings on 300-acre northern Illinois beef farms in 1968 averaged \$19,190 compared with \$12,771 in 1967 and \$14,176

for the 1959-68 average. Since 1958, earnings on this size farm have not exceeded \$13,000 except in 1962, 1965, and 1968. A \$1.31 higher average selling price for cattle sold in 1968, plus higher livestock inventory prices at the end of the year, helped offset the effect of lower corn yields, lower grain prices, and higher operating costs. The 10-year average (1959-68) management returns on beef farms are \$1,441 lower than grain farms of similar size, and \$2,922 lower than hog farms of similar size.

#### Southern Illinois farms

Grain farms. Farm and family earnings on southern Illinois 300-acre grain farms averaged \$8,124 in 1968. This is \$2,855 decline from 1967, and the lowest since 1960. The 18-bushel-per-acre lower corn yield, combined with lower grain prices and the \$573 higher cash operating expenses per farm, resulted in a sharp drop in earnings.

Hog farms. Farm and family earnings on southern Illinois 300-acre hog farms averaged \$12,193, a decrease of \$1,778 from 1967 but still \$1,027 above

the 10-year average (1959-68). Corn and wheat yields were down 22 and 5 bushels per acre respectively from 1967.

Part of the effect of lower crop yields and lower grain prices was offset by higher livestock returns. Hog farms continue to show higher returns for all resources used than grain or dairy farms.

Dairy farms. Farm and family earnings on 300-acre southern Illinois dairy farms in 1968 were \$12,846, a drop of \$4,785 from 1967. This compares with the 10-year average (1959-68) of \$11,053. Most of this decrease resulted from lower corn and wheat yields and from 5 to 20 percent lower grain prices than in 1967. Corn and wheat yields were down 21 and 8 bushel per acre respectively.

Part of the effect of lower crop income and higher cash operating expenses was offset by higher beef and milk prices. A combination crop and livestock enterprise farm has been able to maintain higher earnings on southern Illinois 300-acre farms than grain farms. The 10-year average income levels of dairy and hog farms is \$11,053 and \$11,166 respectively, compared with \$9,371 from the same size grain farms.

#### LIVESTOCK ENTERPRISES

Table 5 shows the returns per \$100 feed fed to various livestock enterprises and the price of corn during each of the past 15 years. Fifteen-year (1954 through 1968) averages are also shown. The difference between the average return figure and \$100 feed cost represents the margin available to pay labor, depreciation on equipment, cash expenses other than feed, and interest on investment, and also to provide for profit.

The margin needed to cover nonfeed costs varies with the kind of livestock and depends on the proportion of total production costs represented by feed. The 15-year averages represent the approximate level of returns at which farmers have been willing to maintain livestock production. This average may not represent break-even returns on all farms because some farmers may discount market prices for some resources used in producing livestock. If a farmer already has facilities for livestock, he need only cover operating costs to continue production. However, when he views livestock production as a new or long-run enterprise, he hopes to cover all costs — fixed and variable — or he may not undertake the enterprise.

As individual farmers try to increase profits, they tend to curtail livestock production when returns per \$100 of feed fed are below the 15-year average and to increase production when returns are above average. This tendency on the part of producers causes supplies of livestock products to fluctuate.

Feeder-cattle returns vary greatly from year to year. Long-run average returns shown here indicate the cattle-feeding business is not paying average market rates for all resources used (see Table 7). Above-

<sup>\*</sup> Fourteen-year average.

average skills are needed in buying, selling, and feeding to meet competition of other uses for time and money on farms feeding cattle. It is difficult to identify cyclic income movements over a 15-year period in the beef-cattle industry because it is more complex and adjusts more slowly than other livestock enterprises.

Dairy and poultry returns fluctuate less than beefcattle returns from year to year. In all three enterprises 15-year average returns are below the margin needed to cover all fixed and variable costs. The implication is that these enterprises compete most favorably on farms with plentiful labor, capital, and management resources that have few alternative uses.

Raising livestock is becoming more competitive. Average profit margins are very narrow. Nonetheless, large numbers of farmers are willing to stay in business as long as their returns cover only operating costs. Expansion plans involving large investments for new facilities should be based on estimated returns that are high enough to cover all costs. Fluctuations in livestock returns can involve a risk in low-return years.

#### Hog enterprises

The information in Table 6 is based on a sample of 677 farms farrowing 10 or more litters per year. Farms

Table 6. — Hog Enterprises, 1968

	A 11 C	Litters f	arrowed

Price received per 100 pounds Feed cost per 100 pounds produced Feed per 100 pounds	\$ 18.54 \$ 10.88	\$ 18.25 \$ 10.85	\$ 18.67 \$ 10.85
produced Farm grains, lb Commercial feed, lb Total concentrates, lb. Pasture (pasture days) Cost per 100 pounds of commercial feeds Cost per 100 pounds of concentrates	342 74 416 .5 \$ 6.14 \$ 2.60	339 73 412 .6 \$ 6.16 \$ 2.60	338 76 414 .4 \$ 6.04 \$ 2.61

were omitted from the sample if the number of hogs purchased exceeded 10 percent of pigs weaned. This eliminated from the sample those farms with combined farrowing and feeder-pig operations. Feederpig enterprise information is included in Table 9. The average size of the hog enterprise on all record-keeping farms has been increasing at the rate of about 3 litters per year, from 41 litters (229 pigs weaned) per farm in 1956 to 77 litters (562 pigs weaned) in 1968.

Returns per \$100 feed fed to hogs were \$170 in 1968. This was a \$16 increase from 1967. In 1968 the average price received per 100 pounds of pork sold was down 31 cents while the average price per bushel of corn fed (see Table 5) was down 15 cents per bushel.

The 1968 hog enterprise records reported in Table 6 were also sorted by the number of litters produced. One group farrowing between 10 and 49 litters averaged 31 litters, while the group farrowing 100 or more litters averaged 167 litters.

There were no significant differences in production efficiency between the two groups. Feed cost per 100 pounds of pork produced was the same for both groups. Prices received for hogs sold by the larger producers were 42 cents higher than those received by the smaller producers.

The nine-year average return above feed cost per litter shown in Table 7 is \$115, \$12 below the 1968 returns. On the basis of detailed cost records, which indicate that feed makes up 70 percent of the total cost of producing hogs, farmers would require returns

Table 7. — Variation in Returns to Livestock-Enterprise Units, 1960-1968

Year	Hogs (lit- ter)	Feeder pigs (175 lb. gain)	Feeder cattle (500 lb. gain)	Dairy cattle (cow)	Beef herd (cow)	Poultry laying flock (hen)

Total nonfeed costs	78	6.12	33	316	86	1.92

<sup>&</sup>lt;sup>a</sup>Includes veterinary costs, taxes on equipment and livestock,

above feed cost of \$78 a litter to pay for all non-feed

Direct cash costs only amounted to \$20 a litter. Since 1961 the average Illinois hog producer has received \$37 return per litter (\$115-\$78) above all feed and nonfeed costs each year. While this return appears to be a profitable one, the modest expansion in hog numbers suggests that a rather large profit margin is required to compensate farmers for the risk and detailed management involved in hog production when compared to other alternative uses for the same resources. Farmers who have the capital and skill required to manage hogs may want to invest more resources in this enterprise.

The costs, returns, and other characteristics of three types of hog enterprises for the 1966-1968 period are shown in Table 8. Returns above feed cost and estimated veterinary, power, buildings, equipment, and interest costs per pig for the complete farrow-to-finish operation averaged \$12.51 for the three-year period. During the same period these returns from the enterprises growing feeder pigs was \$7.28 per pig and from the enterprises finishing feeder pigs was \$3.34, for a combined total of \$10.62. The difference of \$1.89 per pig was caused by the cost of transferring feeder pigs from one farm to another. Greater death losses, higher feed costs, and added marketing costs result from this transfer. There was no difference between the farms growing feeder pigs and the combined farrowing and finishing enterprises in terms of the number of pigs weaned per litter.

Table 8. - Comparison of Feeder Pig Growing, Finishing, and Farrowing and Finishing Enterprises on Illinois Farms, 1966-1968 Averages

<sup>&</sup>lt;sup>a</sup> Includes market and breeding hogs.

fuel and equipment repair costs, and other direct cash expenses, from Table 6, Farm Management Manual, AE-4200.

<sup>b</sup> Estimates are based on feed representing 70 percent of the total cost for hogs, 75 percent for feeder pigs, 85 percent for feeder cattle, 50 percent for dairy, 55 percent for beef cows, and 60 percent for poultry.

b Adapted from Detailed Cost Report for Central and Western Illinois, 1964 and 1965, AERR 85, Dept. Agr. Econ., Univ. Ill. at Urbana-Champaign, 1967.

On farms growing feeder pigs, 1.7 percent of the pigs died after weaning, while 3.8 percent of the pigs died on farms finishing feeder pigs, for a combined total of 5.5 percent. Only 3.4 percent of the pigs died after weaning on farms that combined farrowing and finishing operations.

These data indicate that the farrow-through-finish system earns more profits per pig than the other systems. However, no one system is best for all Illinois farms. Each system requires different proportions of feed, labor, capital, and management. The best choice of a system comes from matching available resources with the requirements for each system, so that the greatest net farm income will be produced.

#### Feeder-cattle and feeder-pig enterprises

Calendar-year operations for feeder-cattle and feeder-pig enterprises are presented in Table 9. These enterprise summaries involve weights and values on partly finished animals purchased in prior years as well as on animals purchased in the current year.

Pork produced per farm from feeder-pig enterprises was 70,706 pounds in 1968 (see Table 9). In units of 175 pounds produced per head, this amounted to 404 head fed per farm in 1968 compared with 224 head in 1958.

Returns above the cost of feed and purchased animals shown in Table 7 for 1960 through 1968 averaged \$6.21 per unit of 175 pounds of gain. This compares with the estimated return of \$6.12 required to cover all of the nonfeed costs. If the very high returns above feed cost in 1965 were excluded in the nine-year average, the average would have been about \$2 per head short of the estimated total returns needed to pay all costs.

Table 9. — Feeder-Cattle and Feeder-Pig Enterprises, 1968

	Feeder cattle	Feeder pigs
Number of farms	332	105
Average per farm Total pounds produced	89,749 \$23,754 \$16,707 \$ 142 2.0 576 \$ 26.97 \$ 26.29 \$ 18.62 600 600 660 131 767	70,706 \$ 9,915 \$ 7,413 \$ 134 2.2 57 \$ 32.85
Pasture (pasture days)	2	• • •

Assuming a 500-pound unit of gain equals one head of feeder cattle, the 89,749 pounds of beef produced per farm in 1968 (Table 9) is 179 head. This is 81 head more cattle fed per farm than in 1958. Returns per \$100 feed fed for feeder-cattle enterprises were \$142 in 1968 compared with \$119 in 1967 and \$124 for the past 15-year average (see Table 5).

The prices paid for feeders bought were 60 cents per 100 pounds higher during 1968 than in 1967, while prices received for cattle sold in 1968 were \$1.31 higher. Average weight purchased remained steady at 576 pounds per head. The lower feed cost of \$18.62 per 100 pounds produced in 1968 compared with \$19.18 in 1967 was due largely to the 15-cent lower market price for corn (see Table 5).

Pounds of concentrates and hay used per 100 pounds of beef produced decreased 47 and 49 pounds respectively since 1960. The pounds of silage used has nearly doubled during the same period. The end result of this shift has been increased production and utilization of crops from a fixed land resource. Mechanization of the silage feeding operation has also contributed to reduced labor per unit of production.

These data do not show the wide variation in profits that exists among cattle-feeding programs. Tables 5, 7, and 9 reflect the composite results of all types of feeder cattle enterprises in Illinois as to quality and age of cattle fed. The data reported are heavily weighted with good-to-choice calves and yearlings as the predominant cattle-feeding system. Many farmers are now feeding more than one drove of cattle each year to provide a better utilization of fixed investments in mechanized feedlots.

Returns above cost of feed and purchased animals shown in Table 7 averaged \$21 for each head of feeder cattle gaining 500 pounds for the nine years 1960 through 1968. During this period returns above feed costs per feeder have ranged from a loss of \$11 in 1963 to a high of \$47 in 1965. Except for 1962, 1965, and 1968, returns above feed cost have been below the estimated \$33 per feeder required to pay for all nonfeed costs for the average cattle feeder.

The direct cash costs exclusive of interest costs associated with cattle feeding average about \$8 per feeder. Returns above feed costs have exceeded the direct cash costs per head for all years except for 1963.

Large numbers of cattle feeders in Illinois are apparently willing to feed cattle if their return is sufficient to cover feed and cash costs but short of paying average market rates for some of the fixed and farm overhead costs.

Farmers' values, goals, and attitudes have been important in maintaining production on the one hand, while the dictates of the market, technological change,

and shifts in basic supply and demand factors are causing the need for change on the other hand. The low returns reflected in this average of all feeder cattle enterprises would suggest that for cattle feeding to be profitable, farmers must produce the kind of beef the consumer wants at the lowest possible costs. Farmers considering expansion of this enterprise on farms where there are no nonmarketable feeds, unemployed labor, or fixed capital investments should budget and plan carefully before they make new investments. New feedlot facilities generally increase direct cash costs when compared with the fixed costs associated with older facilities.

#### **Dairy** enterprises

The minimum size of herd included in this analysis was 10 milk cows. The average size of dairy herd has increased at the rate of about one cow per year since 1957. The total number of milk cows in Illinois has been declining at the rate of about 4 percent a year in this same period, but total pounds of milk produced in the state has been declining only about 2 percent a year. While there are 42 percent fewer milk cows in the state than 10 years ago, the remaining cows are in herds that are 60 percent larger and that produce 23 percent more milk per cow.

Returns per \$100 of feed fed in dairy enterprises in 1968 were \$210, up \$11 from 1967 and one of the highest returns on record (see Table 5). Higher milk and beef prices and lower feed costs are reflected in the 1968 returns.

Dairy farmers have reduced the amount of pasture and increased the amounts of grain and silage fed. Pasture days per unit (1,000 pounds of milk or 100 pounds of beef) remained at 15 days prior to 1959, but since 1960 have declined to 6 days in 1968.

The dairy herds in Table 10 were divided into three groups: herds with no pasture days per animal unit, those with 1 to 119 days, and those with 120 days or more. Each year a few more farmers have been adopting the practice of feeding cows in drylot. Dairy herds with no direct grazing averaged 45.2 cows per farm compared with 31.3 cows per farm where a full pasture season was used.

The main difference among these three groups of dairy herds is the amount of land required per cow to produce roughage. When pasture and hay yields are figured at 150 pasture days and 3 tons per acre respectively, farms with drylot feeding required only 1.6 acres per cow to produce grass-legume forages, while farms with over 120 pasture days per animal unit used 2.9 acres. Additional roughage was obtained through the corn silage on the no-grazing farms.

Part of the additional cost of harvesting roughage to

be fed in drylot is included in the cost of feed. Farmers using the drylot system must relate the higher cost of labor and machinery to the increased returns that may result from the following factors: shifting land from pasture to grain crops; an increase in size of dairy herd on fixed acres of hay and pasture; or higher production per cow.

Return above cost of feed was \$350 per cow in 1968 (Table 7). This compares with the nine-year average of \$250. The returns above feed cost per cow required to pay for all nonfeed costs are estimated to be about \$316 per cow. This assumes that feed represents 50 percent of the total cost of the dairy enterprise while labor and capital make up the other 50 percent.

<sup>&</sup>lt;sup>a</sup> 1,000 pounds of milk or 100 pounds of beef.

Dairy returns above feed costs per cow have been among the highest on record in 1966, 1967, and 1968. Gross returns from the dairy enterprise in 1967 and 1968 have been high enough to pay cash expenses and market prices for all feed, labor, depreciation, and interest on investment. Reduction in the total number of cows in production, combined with steady demand for milk, has helped dairy herds in 1966, 1967, and 1968 provide returns competitive with those from other uses for feed, labor, and capital. As dairy herds become larger and as costs become higher, there is greater need for the dairy enterprise to be managed as a profit-making business.

#### Beef-cow herd

The minimum size of a beef-cow herd included in Table 11 was 10 or more cows. Farms with combinations of cow herds and purchased feeder cattle were not included. In addition to all farms, Table 11 shows an analysis of cow herds where calves were sold at weaning time, comparing them with those where calves were finished to slaughter weights. The average size of cow herd on all farms has changed little since 1956, ranging from 25 to 32 cows. Most Illinois farmers maintain a beef-cow herd as a supplemental enterprise to market nonsalable feeds and labor.

Returns per \$100 feed fed to beef-cow herds in 1968 averaged \$156, up \$18 from 1967. Lower feed costs and higher beef prices during 1968 continued to raise cow herd returns from the low level of 1964.

In 1968 farms that sold calves received \$52 per cow above value of feed fed, and farms that sold cattle at slaughter weights received \$66 per cow above value of feed fed. These returns have increased each year since the low returns of only \$6 per cow in 1964. The higher returns for those who sold slaughter cattle must be balanced against the added costs for labor, buildings, and capital required to feed out the calves produced from the cow herd.

#### Poultry enterprises

The minimum size of flock included in Table 12 is 100 hens. The average size of flock, omitting farms with less than 100 hens, has increased from 353 hens in 1957 to 1,301 in 1968. In the same period, pounds of feed concentrates per dozen eggs, or 1½ pounds of weight produced, have declined steadily each year from 6.8 in 1957 to 5.3 pounds in 1968. This change in

Table 12. — Poultry Enterprises, 1968

<sup>&</sup>lt;sup>a</sup> One dozen eggs or 1.5 pounds of weight produced.

the feed-to-product ratio over the past 10 years is significant to the poultry enterprise.

For 1968 the feed cost per dozen eggs was 16 cents. The return above feed cost per hen of \$1.98 in 1968 was \$1.06 above the 1967 return and is near the nine-year average of \$1.93 (Table 7).

Farms with over 2,000 hens had returns above feed cost per hen of \$2.31 compared with only 63 cents on farms with 100 to 299 hens (Table 12). This difference may not reflect the actual contribution of poultry laying flocks to farm income, since small flocks may utilize inputs of labor, equipment, and buildings that have limited alternative uses. However, the higher production per hen on the farms with larger flocks indicates better management and a potentially higher return for labor and capital.

#### Sheep enterprises

Sheep production is a minor enterprise on record-keeping farms. The minimum size of enterprise in Table 13 was set at 3 animal units. One animal unit of sheep is defined as 750 pounds of liveweight. Returns per \$100 feed fed in 1968 were \$133 for native

flocks. Pounds of wool and mutton produced per farm have remained fairly constant for the past 10 years. The majority of Illinois farmers who keep sheep do so as a supplemental enterprise to market nonsalable feeds and labor.

#### DEFINITION OF TERMS AND ACCOUNTING MEASURES

#### Soil-productivity rating

An average index representing the inherent productivity (low level of management) of all tillable land in the farm. Individual soil types on each farm are assigned an index ranging downward from 100.

#### Type of farm

Sampling technique. The records in each size group for northern Illinois were sampled to provide a proportional representation of all farms of that size range according to the 1964 census.

Grain farms. Farms where the value of feed fed was *less* than one-half of the feed and grain returns and value of feed fed to dairy or poultry was not more than one-sixth of the feed and grain returns.

Hog or beef farms. Farms where the value of feed fed was more than one-half of the feed and grain returns and either hog or beef-cattle enterprises received more than one-half of the value of feed fed.

Dairy or poultry farms. Farms where the value of feed fed was more than one-half of feed and grain returns and either dairy or poultry enterprises received more than one-third of the value of feed fed.

#### Cost items

Value of feed fed. Includes grains priced per bushel

at the farm average as follows: corn — \$1.02; oats — 65 cents; barley — 84 cents; soybeans — \$2.52; rye — \$1.00; wheat — \$1.25. Commercial feeds were priced at actual cost, hay and silage at farm values, and pasture at 13 cents per animal unit pasture day. A pasture day represents an intake of approximately 20 to 25 pounds of dry matter. It has been defined as

16 pounds of total digestible nutrients (TDN) from pasture.

Cash operating expenses. Includes annual cash outlays for nondepreciable items of fertilizer, machinery repairs, machine hire, gas and oil, electricity and telephone, farm share of auto, hired labor, seed and crop expense, taxes, building repairs, livestock, and miscellaneous expense. It does not include purchased feed and livestock since these have been deducted from gross receipts in computing the value of farm production.

Machinery and equipment. Includes depreciation, repairs, machine hire, gas and oil, electricity and telephone, and farm share of auto.

Labor. Includes hired labor plus family and operator's labor charged in 1968 at \$350 and \$325 a month respectively for northern and southern Illinois.

Interest charge on capital. Interest charged at 6 percent on January 1 inventory of remaining capital investment in grain, livestock, machinery and auto, buildings, and soil fertility, plus 4 percent interest on bare land priced at current land values.

Total nonfeed costs. Includes cash operating expenses, depreciation, and charges for unpaid labor and interest. Purchased feeds and livestock are omitted.

Value of land (current basis). A basic value on bare land is established for each farm according to the soil-productivity rating. This basic value is adjusted each year according to the index of land prices in Illinois as reported by the USDA.

#### Return items

Feed and grain returns. The sum of grain and feed sales, value of all feed fed (except milk), and change in value of feed and grain inventories less the value of feed purchased.

Value of farm production. Total cash sales of products and services, less purchased feed and livestock, plus change in inventory values of grain and livestock, plus value of farm products consumed.

Farm and family earnings. Value of farm production less cash operating expenses and depreciation. This figure includes the return to the farm and family for unpaid labor, interest on invested capital, and returns to management.

Labor and management earnings. Farm and family earnings less the value of family labor and interest charge on capital invested. This is the residual return to operator's labor and management efforts.

Capital and management earnings. Farm and family earnings less a charge for all unpaid labor.

Management returns. The residual surplus left after a charge for unpaid labor and interest charge on capital are deducted from farm and family earnings.
